It started as an ordinary day at work for 51-year-old husband and father, Graeme Webb, who had no history of heart disease. As the day progressed, Graeme began experiencing a strange tingling in his mouth and made the decision to leave work. Upon arriving home, the discomfort began to worsen and he called for an ambulance. The last thing he remembers is the ambulance arriving at the Emergency Department.

Arriving at Liverpool Hospital

Graeme arrived in the Emergency Department of Liverpool Hospital at 2.00 p.m. and went into cardiac arrest ten minutes later. Dr. Trudi Davis immediately moved him to the resuscitation bay and commenced cardiopulmonary resuscitation (CPR). He was in ventricular fibrillation (VF) and defibrillation was attempted but was unsuccessful.

Faced with a protracted resuscitation, Dr. Davis made the decision to use Physio-Control LUCAS chest compression system in order to provide consistent, high quality CPR and enable the medical and nursing staff to perform critical resuscitation management functions. “Graeme didn’t respond to the first defibrillation so we then took the decision to apply LUCAS because that would provide good quality CPR and allow us to defibrillate without interruption while we considered reversible causes.”

Once the LUCAS device commenced CPR it immediately provided Dr. Davis with, as she puts it, “enormous cognitive space to think about all the other things I needed to think about to get Graeme the appropriate treatment, rather than being preoccupied with rotating staff through cycles of manual CPR.”

"It is very rare to see a single piece of equipment make a fundamental difference to a patient’s outcome. I am ecstatic about the result we got for this patient.”  
- Dr. Christian Mussap, Interventional Cardiologist

Dr. Davis contacted the Interventional Cardiologist, Dr. Christian Mussap, in the Cardiac Catheterisation Lab (cath lab) to request that Webb be assessed for percutaneous coronary intervention (PCI). Clinical Nurse Consultant Kathryn Spears made arrangements for him to be transferred from the emergency department to the cath lab with the LUCAS device providing CPR throughout. She said that the LUCAS allowed staff to focus on intubating the patient and administering medications without having to worry about the quality of CPR the patient was receiving.

“It’s about trying to find a balance to make sure everyone’s getting the best care possible and LUCAS 2 certainly supports that in terms of ensuring the quality of CPR is consistent and is able to be delivered irrespective of whether the staff are tired and irrespective of how long the resuscitation has been going,” she said.

“It was a busy area. We had a lot of people wanting to help, but it was quite controlled in the actual bay itself because we didn’t need any additional staff there to provide manual CPR,” said Spears.

The Procedure

Previously at Liverpool Hospital, it has been highly unusual for a patient to be transported to the cath lab unless they have ‘Return of Spontaneous Circulation’ (ROSC) before transport. The journey takes up to ten minutes and requires staff members to be performing CPR while the patient is being moved, presenting significant injury risks to patient and staff.

Acting Director of the Emergency Department, Dr. Shamus Shepherd, said that in his experience, if the patient didn’t get ROSC following a reasonable period of CPR and advanced life support, then they were invariably pronounced deceased.

“To be able to put LUCAS on a patient and not worry about rotating my staff through the job of CPR buys me enormous cognitive space to think about all the other things I need to think about during a resuscitation in order to provide the optimum and most appropriate treatment for the patient.”

- Dr. Trudi Davis

The Outcome

Graeme Webb has been fondly dubbed, ‘The Miracle Man’ by the Liverpool Hospital staff. He was discharged from hospital eight days later and returned to work within three months of his cardiac arrest. He has since made the decision to spend more time with his family.

A Survivor Returns

Three months after being discharged from hospital, Graeme was invited back by Liverpool Hospital staff to meet with the team involved in his resuscitation and the Hospital Auxiliary volunteers who had raised funding to purchase the LUCAS 2 used throughout Graeme’s resuscitation and PCI.

The Recovery

Dr. Trudi Davis says that the most surprising part of Graeme’s story was that he woke up neurologically intact soon after the procedure, despite many patients in similar circumstances needing long periods of time on life support in the Intensive Care Unit (ICU).

Dr. Mussap said that when he went to visit Graeme in ICU the next morning he discovered he had already been transferred to Coronary Care and was sitting up in bed talking to his teenage son and daughter. Dr. Davis also remembers talking to Graeme and his family in ICU the next morning where they were all in tears, such was the huge emotional relief.

Interviewed later, Dr. Mussap was adamant that Graeme was truly lucky to have survived his cardiac arrest, but he felt it was the survival neurologically intact that was absolutely remarkable. “I was skeptical, as patients in this situation usually do badly” Dr. Mussap said. “However, this is a game-changer and as a result we have changed our policy regarding transporting patients in cardiac arrest to the cath lab.”

More Information

For information about Liverpool Hospital Cardiac Catheterization Lab tests and the LUCAS chest compression system under fluoroscopy, please ask your sales representative for Physio-Control product comparison document 3319603 (LUCAS vs. AutoPulse under Fluoroscopy).
